(57) **ABSTRACT**

(22) **Filed:** **Jun. 1, 2006**

A method for growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices, comprising identifying desired material properties for a particular device application, selecting a semipolar growth orientation based on the desired material properties, selecting a suitable substrate for growth of the selected semipolar growth orientation, growing a planar semipolar (Ga,Al,In,B)N template or nucleation layer on the substrate, and growing the semipolar (Ga,Al,In,B)N thin films, heterostructures or devices on the planar semipolar (Ga,Al,In,B)N template or nucleation layer. The method results in a large area of the semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices being parallel to the substrate surface.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention is related to semiconductor materials, methods, and devices, and more particularly, to the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices.

2

2. Description of the Related Art

(Note: This application references a number of different publications as indicated throughout the specification by one or more reference numbers within brackets, e.g., [Ref. x]. A list of these different publications ordered according to these reference numbers can be found below in the section entitled "References." Each of these publications is incorporated by reference herein.)

The usefulness of gallium nitride (GaN) and alloys of (Ga,Al,In,B)N has been well established for fabrication of visible and ultraviolet optoelectronic devices and high-power electronic devices. As shown in FIG. 1, current state-of-the-art nitride thin films, heterostructures, and devices are grown along the [0001] axis **102** of the wurtzite nitride crystal structure **100**. The total polarization of such films consists of spontaneous and piezoelectric polarization contributions, both of which originate from the single polar [0001] axis **102** of the wurtzite nitride crystal structure **100**. When nitride heterostructures are grown pseudomorphically, polarization discontinuities are formed at surfaces and interfaces within the crystal. These discontinuities lead to the accumulation or depletion of carriers at surfaces and interfaces, which in turn produce electric fields. Since the alignment of these built-in electric fields coincides with the typical [0001] growth direction of nitride thin films and heterostructures, these fields have the effect of "tilting" the energy bands of nitride devices.

In c-plane wurtzite (Ga,Al,In,B)N quantum wells, the "tilted" energy bands **104** and **106** spatially separate the hole wavefunction **108** and the electron wavefunction **110**, as illustrated in FIG. 1. This spatial charge separation reduces the oscillator strength of radiative transitions and red-shifts the emission wavelength. These effects are manifestations of the quantum confined Stark effect (QCSE) and have been thoroughly analyzed for nitride quantum wells [Refs. 1-4]. Additionally, the large polarization-induced fields can be partially screened by dopants and injected carriers [Refs. 5, 6], so the emission characteristics can be difficult to engineer accurately.

Furthermore, it has been shown that pseudomorphic biaxial strain has little effect on reducing effective hole masses in c-plane wurtzite (Ga,Al,In,B)N quantum wells [Ref. 7]. This is in stark contrast to the case for typical III-V zinc-blende InP- and GaAs-based quantum wells, where anisotropic strain-induced splitting of the heavy hole and light hole bands leads to a significant reduction in the effective hole masses. A reduction in effective hole masses leads to a substantial increase in the quasi-Fermi level separation for any given carrier density in typical III-V zinc-blende InP- and GaAs-based quantum wells. As a direct consequence of this increase in quasi-Fermi level separation, much smaller carrier densities are needed to generate optical gain [Ref. 8]. However, in the case of the wurtzite nitride crystal structure, the hexagonal symmetry and small spin-orbit coupling of the nitrogen atoms in biaxially strained c-plane nitride quantum wells produces negligible splitting of the heavy hole and light hole bands [Ref. 7]. Thus, the effective mass of holes remains much larger than the effective mass of electrons in biaxially strained c-plane nitride quantum wells, and very high carrier densities are needed to generate optical gain.

One approach to eliminating polarization effects and decreasing effective hole masses in (Ga,Al,In,B)N devices is to grow the devices on nonpolar planes of the crystal. These include the {11 $\bar{2}$ 0} planes, known collectively as a-planes, and the {1 $\bar{1}$ 00} planes, known collectively as m-planes. Such planes contain equal numbers of gallium and nitrogen atoms per plane and are charge-neutral. Subsequent non-polar layers are equivalent to one another so the bulk crystal will not be

polarized along the growth direction. Moreover, it has been shown that strained nonpolar InGaN quantum wells have significantly smaller hole masses than strained c-plane InGaN quantum wells [Ref. 9]. Nevertheless, despite advances made by researchers at the University of California and elsewhere [Refs. 10-15], growth and fabrication of nonpolar (Ga,Al,In,B)N devices remains challenging and has not yet been widely adopted in the nitride industry.

Another approach to reducing polarization effects and effective hole masses in (Ga,Al,In,B)N devices is to grow the devices on semipolar planes of the crystal. The term “semipolar plane” can be used to refer to any plane that cannot be classified as c-plane, a-plane, or m-plane. In crystallographic terms, a semipolar plane would be any plane that has at least two nonzero h, i, or k Miller indices and a nonzero l Miller index.

Growth of semipolar (Ga,Al,In,B)N thin films and heterostructures has been demonstrated on the sidewalls of patterned c-plane oriented stripes [Ref. 16]. Nishizuka et al. have grown $\{11\bar{2}2\}$ InGaN quantum wells by this technique. However, this method of producing semipolar nitride thin films and heterostructures is drastically different than that of the current disclosure; it is an artifact of epitaxial lateral overgrowth (ELO). The semipolar facet is not parallel to the substrate surface and the available surface area is too small to be processed into a semipolar device.

The present invention describes a method for the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices on suitable substrates or planar (Ga,Al,In,B)N templates in which a large area of the semipolar film is parallel to the substrate surface. In contrast to the micrometer-scale inclined-facet growth previously demonstrated for semipolar nitrides, this method should enable large-scale fabrication of semipolar (Ga,Al,In,B)N devices by standard lithographic methods.

Compared with zinc-blende InP- and GaAs-based quantum well heterostructures and devices, würtzite c-plane (Ga,Al,In,B)N quantum well heterostructures and devices require higher carrier densities to generate optical gain. This can be attributed to the presence of large polarization-induced electric fields and inherently large effective hole masses [Refs. 17, 18]. Therefore, reduction of built-in electric fields and effective hole masses is essential for the realization of high-performance (Ga,Al,In,B)N devices.

The design of typical InP- and GaAs-based heterostructure devices usually involves varying thin film parameters such as composition, thickness, and strain. By varying these parameters, it is possible to change the electronic and optical properties of individual epitaxial layers, such as bandgap, dielectric constant, and effective hole mass. Although not typically employed in InP- and GaAs-based device design, altering the crystal growth orientation can also affect the electronic and optical properties of individual epitaxial layers. In particular, altering the crystal growth orientation can reduce polarization effects and effective hole masses in nitride thin films and heterostructures. To accommodate this novel design parameter, we have invented a method for the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices. By properly selecting the correct substrate or semipolar template for crystal growth, the optimum combination of net polarization and effective hole mass can be chosen to suit a particular device application.

As an illustration of the effects of altering the crystal growth orientation, the piezoelectric polarization can be calculated and plotted as a function of the angle between a general growth direction and the c-axis for compressively strained $\text{In}_x\text{Ga}_{1-x}\text{N}$ quantum wells [Refs. 9, 18-20]. FIG. 2

shows the relationship between the conventional coordinate system (x, y, z) for c-plane crystal growth and a new coordinate system (x', y', z') for a general crystal growth orientation. The conventional coordinate system (x, y, z) can be transformed into the new coordinate system (x', y', z') by using a rotation matrix,

$$U = \begin{pmatrix} \cos\theta\cos\phi & \cos\theta\sin\phi & -\sin\theta \\ -\sin\phi & \cos\phi & 0 \\ \sin\theta\cos\phi & \sin\theta\sin\phi & \cos\theta \end{pmatrix} \quad (1)$$

where ϕ and θ represent the azimuthal and polar angles of the new coordinate system relative to the [0001] axis, respectively. As shown in FIG. 2, the z-axis corresponds to the [0001] axis **102** and the z'-axis **200** corresponds to the new general crystal growth axis. For calculating physical parameters, dependence on the azimuthal angle (ϕ) **202** can be neglected because the piezoelectric effect in würtzite materials shows monoaxial isotropic behavior along the [0001] axis [Ref. 21]. Thus, a family of equivalent semipolar planes can be uniquely represented by a single polar angle (θ) **204**, referred to hereafter as simply the crystal angle **204**. The crystal angles **204** for polar, non-polar, and a few selected semipolar planes are shown in Table 1 below.

TABLE 1

List of polar, non-polar, and selected semipolar planes with corresponding crystal angles.	
Plane	Crystal Angle (θ)
{0001}	0°
{10T4}	25.1°
{10T3}	32.0°
{10T2}	43.2°
{20T3}	51.4°
{11T2}	58.4°
{10T1}	62.0°
{20T1}	75.0°
{1T00}	90°
{11T0}	90°

As expected, the {0001} planes correspond to $\theta=0^\circ$, the $\{1\bar{1}00\}$ and $\{11\bar{2}0\}$ planes correspond to $\theta=90^\circ$, and the semipolar planes correspond to $0^\circ<\theta<90^\circ$.

The piezoelectric polarization of a crystal is determined by the strain state of the crystal. For heteroepitaxial growth of non-lattice matched crystal layers, the strain state of the individual layers is determined by the biaxial stress in the growth plane.

For a general crystal growth orientation along the z'-axis **200**, the biaxially stress components $\sigma_{x'x'}$ and $\sigma_{y'y'}$ in the growth plane can be transformed into the conventional (x, y, z) coordinate system through the transformation matrix U. This allows the determination of the strain state and piezoelectric polarization in (x, y, z) coordinates. Thus, the piezoelectric polarization in (x, y, z) coordinates varies as function of the crystal angle (θ) **204** through the transformation matrix U. For a general crystal growth orientation, the piezoelectric polarization can be obtained by taking the scalar product between the polarization vector P in (x, y, z) coordinates and the unit vector \hat{z}' along the general crystal growth direction:

$$P'_z = P \cdot \hat{z}' = P_x \sin\theta + P_z \cos\theta \quad (2)$$

where P_x and P_z represent the components of the piezoelectric polarization in (x, y, z) coordinates and are in general dependent on the crystal angle (θ) **204**, as described above.

FIG. 3 illustrates the piezoelectric polarization **300** as a function of the angle between the growth direction and the c-axis for compressively strained $\text{In}_x\text{Ga}_{1-x}\text{N}$ quantum wells with unstrained GaN barriers [Refs. 9, 18-20]. As expected, the polarization **300** is maximum for c-plane growth ($\theta=0^\circ$) and zero for a-plane or m-plane growth ($\theta=90^\circ$). In between these two limits, the polarization changes sign once and is equal to zero at some angle θ_0 **302**. The exact value of θ_0 **302** is dependent on the values of several physical parameters such as the piezoelectric tensors and elastic constants, many of which are largely unknown at present [Refs. 21-25].

Much like piezoelectric polarization effects, effective hole masses for compressively strained $\text{In}_x\text{Ga}_{1-x}\text{N}$ quantum wells can also be substantially reduced by altering the crystal growth orientation. Theoretical results [Ref. 9] show that the effective hole masses for compressively strained $\text{In}_x\text{Ga}_{1-x}\text{N}$ quantum wells should decrease monotonically as the crystal angle is increased due to anisotropic strain-induced splitting of the heavy hole and light hole bands. Thus, growing compressively strained $\text{In}_x\text{Ga}_{1-x}\text{N}$ quantum wells on semipolar orientations should significantly reduce effective hole masses, especially on orientations with large crystal angles.

SUMMARY OF THE INVENTION

The present invention describes a method for the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices. These structures may be grown either directly on suitable substrates or on semipolar (Ga,Al,In,B)N template layers pre-deposited on the substrate. Vapor phase epitaxy techniques, such as metalorganic chemical vapor deposition (MOCVD) and hydride vapor phase epitaxy (HVPE), are used to grow the semipolar (Ga,Al,In,B)N structures. However, the invention is equally applicable to semipolar (Ga,Al,In,B)N thin film, heterostructure, and device growth by molecular beam epitaxy (MBE) or any other suitable growth technique.

Growth of semipolar nitride thin films and heterostructures offers a means of reducing polarization effects and effective hole masses in wurtzite nitride device structures. The term nitrides refers to any alloy composition of the (Ga,Al,In,B)N semiconductors having the formula $\text{Ga}_w\text{Al}_x\text{In}_y\text{B}_z\text{N}$ where $0 \leq w \leq 1$, $0 \leq x \leq 1$, $0 \leq y \leq 1$, $0 \leq z \leq 1$, and $w+x+y+z=1$. Current commercially-available nitride devices are grown along the polar [0001] c-direction. The resulting polarization-induced electric fields and large effective hole masses are detrimental to the performance of state-of-the-art nitride optoelectronic devices.

Growth of these devices along a semipolar direction could significantly improve device performance by reducing built-in electric fields and effective hole masses. Reducing built-in electric fields decreases spatial charge separation in nitride quantum wells. Likewise, reducing effective hole masses decreases the carrier densities required to generate optical gain in nitride laser diodes.

BRIEF DESCRIPTION OF THE DRAWINGS

Referring now to the drawings in which like reference numbers represent corresponding parts throughout:

FIG. 1 is an illustration of band bending in compressively strained $\text{In}_x\text{Ga}_{1-x}\text{N}$ quantum wells due to polarization-induced electric fields.

FIG. 2 illustrates the relationship between the conventional coordinate system (x, y, z) for c-plane crystal growth and the transformed coordinate system (x', y', z') for a general crystal

growth orientation. The azimuthal and polar angles are indicated by ϕ and θ , respectively.

FIG. 3 is a graph that illustrates piezoelectric polarization as a function of the angle between the growth direction and the c-axis for compressively strained $\text{In}_x\text{Ga}_{1-x}\text{N}$ quantum wells with unstrained GaN barriers.

FIG. 4 is a flowchart outlining the salient steps for the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices. This flowchart illustrates how a number of different growth methods and sequences can be used within the scope of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

In the following description of the preferred embodiment, reference is made to the accompanying drawings that form a part hereof, and in which is shown by way of illustration a specific embodiment in which the invention may be practiced. It is to be understood that other embodiments may be utilized and structural changes may be made without departing from the scope of the present invention.

OVERVIEW

The present invention comprises a method for the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices. The flowchart **400** in FIG. **4** summarizes the salient steps for the growth of semipolar (Ga,Al,In,B)N thin films and heterostructures.

Steps **402** and **404** outline a top-down device design procedure used for selecting a semipolar growth orientation. First, the desired material properties (piezoelectric polarization, effective hole mass, etc.) for a particular device application need to be identified as shown in step **402**. Based on these desired properties, the semipolar orientation with the optimum combination of material properties should be selected for growth of the semipolar (Ga,Al,In,B)N thin films and heterostructures in step **404**. This top-down device design procedure is of course an idealization; it presumes that the crystal quality for all semipolar orientations is equal. Adjustments in the device design procedure should be made to conform with actual practice.

After choosing the optimum semipolar growth orientation, the appropriate substrate needs to be selected in step **406**. This substrate would ideally be a free-standing semipolar nitride wafer having a composition lattice matched to the structure to be grown. More often, though, the substrate will be a foreign material, such as MgAl₂O₄ (spinel) or Al₂O₃ (sapphire). The foreign substrate may optionally be coated with a nitride template layer by any suitable growth technique, including, but not limited to, HVPE, MOCVD, MBE, liquid phase epitaxy (LPE), chemical beam epitaxy (CBE), plasma-enhanced chemical vapor deposition (PECVD), sublimation, or sputtering. The composition of the template layer need not exactly match that of the structure to be deposited. The thickness of the template layer may range from a few nanometers (this would be termed a nucleation or buffer layer) to tens or hundreds of micrometers. While not required, the use of templates will generally improve uniformity and yield of semipolar nitride devices. For illustrative purposes, without limiting the scope of the invention, the remainder of this disclosure will describe the use of HVPE-grown semipolar GaN templates for the practice of the invention.

After the substrate or template has been selected, it is loaded into a reactor for growth of the desired semipolar (Ga,Al,In,B)N thin films and heterostructures in step **408**. Suitable growth methods used in steps **410-418** for the practice of this invention include, but are not limited to, HVPE, MOCVD, MBE, LPE, CBE, PECVD, sublimation, sputtering, or any other vapor deposition method. For illustrative purposes, the remainder of this disclosure will describe the growth of semipolar thin films and heterostructures by MOCVD. However, this focus should not be construed as a limitation on the applicability of the invention to other growth techniques. Finally, after the semipolar (Ga,Al,In,B)N structure has been grown, the crystal is removed from the thin film growth reactor and processed into semipolar devices in step **420**.

TECHNICAL DESCRIPTION

The present invention, which describes the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices, involves the following elements:

1. Identification of the desired material properties for a particular device application.
2. Selection of the semipolar orientation with the optimum combination of material properties.
3. Selection of a suitable substrate or template for the growth of the desired semipolar orientation.
4. Growth of the semipolar thin films, heterostructures, and devices by a suitable growth technique.

As discussed above, the practice of the invention is enhanced by the use of thick planar semipolar GaN templates grown by HVPE. To date, we have successfully grown several different planar semipolar GaN template orientations by HVPE. The details of the template growth have been disclosed separately; for reference please see U.S. Provisional Patent Application Ser. No. 60/660,283, entitled "TECHNIQUE FOR THE GROWTH OF PLANAR SEMI-POLAR GALLIUM NITRIDE," filed on Mar. 10, 2005, by Troy J. Baker, Benjamin A. Haskell, Paul T. Fini, Steven P. DenBaars, James S. Speck, and Shuji Nakamura, which application is incorporated by reference herein. In summary, we have experimentally demonstrated four examples of planar semipolar nitride templates:

1. {10 $\bar{1}$ 1} GaN on {100} spinel miscut in specific directions
2. {10 $\bar{1}$ 3} GaN on {110} spinel
3. {11 $\bar{2}$ 2} GaN on {1-100} sapphire
4. {10 $\bar{1}$ 3} GaN on {1-100} sapphire

The crystal quality of these semipolar planes shows little dependence on growth temperature and pressure. The {10 $\bar{1}$ 1} and {10 $\bar{1}$ 3} orientations have been grown at pressures between 10 Torr and 1000 Torr and at temperatures between 900° C. and 1200° C. with little effect on overall crystal quality. This wide range of pressure and temperature shows that these semipolar planes are very stable when grown on the specified substrates. The epitaxial relationships between the particular semipolar planes and specified substrates hold true regardless of the type of growth system used to fabricate the films. However, the optimal reactor conditions for growing these planes will vary according to individual reactor designs and growth methods.

Using these planar HVPE-grown semipolar GaN layers as templates for the growth of semipolar (Ga,Al,In,B)N thin films and heterostructures by MOCVD, we have grown and fabricated semipolar (Ga,Al,In,B)N LEDs on several different semipolar orientations. In particular, we have successfully demonstrated semipolar LEDs on {10 $\bar{1}$ 1} GaN templates on {100} spinel, on {10 $\bar{1}$ 3} GaN templates on {1-100} sapphire, and on {10 $\bar{1}$ 3} GaN templates on {110} spinel.

As shown in FIG. **5**, the first exemplary semipolar LED structure was re-grown by MOCVD on a 10 μ m-thick HVPE-grown {10 $\bar{1}$ 1} GaN template **502** on a {100} spinel substrate **504**. The re-growth, carried out in a vertical MOCVD reactor, began with a 2.0 μ m Si-doped n-type GaN base layer **506**. The active region **508** consisted of a 5 period multiple quantum well (MQW) stack with 16 nm Si-doped GaN barriers and 4 nm InGaN quantum wells. A 16 nm undoped GaN barrier **510** was deposited at low temperature to cap the InGaN MQW structure in order to prevent desorption of InGaN from the active region later in the growth. A 300 nm Mg-doped p-type GaN layer **512** was then deposited. The structure was capped with a 40 nm heavily Mg-doped p⁺-type GaN contact layer **514**.

Following the growth, $300 \times 300 \mu\text{m}^2$ diode mesas were defined by chlorine-based reactive ion etching (RIE). Pd/Au (20/200 nm) and Al/Au (20/200 nm) were used as p-type GaN and n-type GaN contacts **516** and **518**, respectively. A schematic cross-section of the semipolar LED structure, and the $\{10\bar{1}1\}$ plane **520**, are shown in FIG. 5. The electrical and luminescence characteristics of the diode were measured by on-wafer probing of the devices. The current-voltage (I-V) characteristic **600** of a typical LED is shown in FIG. 6. Relative optical power measurements under direct current (dc) conditions were obtained from the backside emission through the spinel substrate onto a calibrated broad area Si photodiode. The electroluminescence (EL) spectra and the optical power emission of the LEDs were measured as a function of drive current as shown in FIGS. 7 and 8, respectively. All measurements were carried out at room temperature.

As shown in FIG. 6, the I-V characteristic **600** of the diode exhibited a low turn-on voltage of 3.1 V with a series resistance of 6.9Ω . EL spectra were also measured at drive currents ranging from 30 to 200 mA. As shown in FIG. 7, the devices show emission spectra **700-710** in the blue spectral range at 439 nm for all drive currents with no observable peak shift. The emission spectra **700-710** correspond to the drive currents 30 mA-200 mA respectively. The absence of a blue-shift in the emission peak with increasing drive current is in contrast to the commonly observed phenomenon of a blue shift in c-plane LEDs operating in this wavelength range and similar drive current range.

Finally, the on-wafer output power and external quantum efficiency were measured as a function of the dc drive current. As shown in FIG. 8, the output power **800** increased approximately linearly as the drive current was increased from 10 mA to 300 mA. The output power at 20 mA forward current was $11 \mu\text{W}$, corresponding to an external quantum efficiency (EQE) **802** of 0.02%. DC power as high as $630 \mu\text{W}$ was measured for a drive current of 300 mA. The EQE increased as the drive current was increased, attaining a maximum of 0.081% at 200 mA, and then decreased slightly as the forward current was increased beyond 200 mA. The absence of a significant decrease in the EQE with increasing drive current is in contrast to the commonly observed phenomenon of a significant decrease in the EQE in c-plane LEDs operating in this wavelength range and similar drive current range.

Although not presented here, photoluminescence (PL) spectra were also compared for the blue (~ 439 nm peak) semipolar LEDs grown on $\{10\bar{1}1\}$ GaN templates on $\{100\}$ spinel with co-loaded c-plane LEDs grown on $\{0001\}$ GaN templates on $\{0001\}$ sapphire. Co-loaded implies that the c-plane template was loaded into the MOCVD reactor at the same time as the semipolar template and that the two templates were resting on the same susceptor during the growth. The PL spectra for the semipolar LEDs were very similar to the PL spectra for the co-loaded c-plane LEDs, suggesting that the indium incorporation efficiency of semipolar $\text{In}_x\text{Ga}_{1-x}\text{N}$ thin films and c-plane $\text{In}_x\text{Ga}_{1-x}\text{N}$ thin films is comparable. This agrees with previous studies of lateral epitaxial overgrowth along semipolar facets which indicate that there is strong impurity incorporation along semipolar planes [Refs. 26, 27].

In addition to the blue (~ 439 nm peak) LEDs grown on $\{10\bar{1}1\}$ GaN templates on $\{100\}$ spinel, FIG. 9 illustrates a green (~ 525 nm peak) LED **900** grown on a $\{10\bar{1}3\}$ GaN template **902** on $\{1\bar{1}00\}$ sapphire substrate **904**. This semipolar LED structure **900** was re-grown by MOCVD on a $10 \mu\text{m}$ -thick HVPE-grown $\{10\bar{1}3\}$ GaN template **902** on $\{1\bar{1}00\}$ sapphire **904**. The re-growth, carried out in a conventional horizontal-flow MOCVD reactor, began with a 500 nm Si-doped n-type

GaN base layer **906**. The active region **908** consisted of a 5 period multiple quantum well (MQW) stack with 8 nm undoped GaN barriers and 4 nm InGaN quantum wells. A 20 nm Mg-doped p-type AlGaIn barrier **910** was deposited at low temperature to cap the InGaIn MQW structure in order to prevent desorption of InGaIn from the active region **908** later in the growth. The structure was capped with 200 nm of Mg-doped p-type GaN **912**.

Following the growth, $300 \times 300 \mu\text{m}^2$ diode mesas were defined by chlorine-based RIE. Pd/Au (5/6 nm) and Ti/Al/Ni/Au (20/100/20/300 nm) were used as p-type GaN and n-type GaN contacts, **914** and **916**, respectively. A schematic cross-section of the semipolar LED structure, and the $\{10\bar{1}3\}$ plane **918**, are shown in FIG. 9. The electrical and luminescence characteristics of the diode were measured by on-wafer probing of the devices. The I-V characteristic **1000** of a typical LED is shown in FIG. 10. Relative optical power measurements under direct current (dc) conditions were obtained from backside emission through the sapphire substrate onto a calibrated broad area Si photodiode. The EL spectra and the optical power emission of the LEDs were measured as a function of driving current as shown in FIGS. 11 and 12, respectively. All measurements were carried out at room temperature.

As shown in FIG. 10, the I-V characteristic **1000** of the diode exhibited a low turn-on voltage of 3.2 V with a series resistance of 14.3Ω . EL spectra were also measured at drive currents ranging from 30 to 200 mA. As shown in FIG. 11, the EL spectra **1100** show that the device **900** emitted in the green spectral range, shifting slightly from 528 nm at 20 mA to 522 nm at 200 mA. The absence of a significant blue-shift in the emission peak with increasing drive currents is in contrast to the commonly observed phenomenon of a considerable blue-shift in c-plane LEDs working at this wavelength range and similar drive current range.

The on-wafer output power and external quantum efficiency were also measured as a function of the dc drive current. As shown in FIG. 12, the output power **1200** increased approximately linearly as the drive current was increased from 10 mA to 250 mA. The output power **1200** at 20 mA forward current was $19.3 \mu\text{W}$, corresponding to an external quantum efficiency (EQE) **1202** of 0.041%. DC power as high as $264 \mu\text{W}$ was measured for a drive current of 250 mA. The EQE **1202** increased as the drive current was increased, attaining a maximum of 0.052% at 120 mA, and then decreased slightly as the forward current was increased beyond 120 mA. The absence of significant decrease in the EQE **1202** with increasing drive currents is in contrast to the commonly observed phenomenon of a significant decrease in the EQE **1202** in c-plane LEDs working at this wavelength range and similar drive current range.

Finally, FIG. 13 illustrates a blue (~ 440 nm peak) semipolar LED **1300** on a $\{10\bar{1}3\}$ GaN template **1302** on $\{110\}$ spinel substrate **1304**. The re-growth, carried out in a vertical MOCVD reactor, began with a $2.0 \mu\text{m}$ Si-doped n-type GaN base layer **1306**. The active region **1308** consisted of a 5 period multiple quantum well (MQW) stack with 16 nm Si-doped GaN barriers and 4 nm InGaIn quantum wells. A 16 nm undoped GaN barrier **1310** was deposited at low temperature to cap the InGaIn MQW structure in order to prevent desorption of InGaIn from the active region **1308** later in the growth. A 300 nm Mg-doped p-type GaN layer **1312** was then deposited. The structure was capped with a 40 nm heavily doped p⁺-GaIn contact layer **1314**.

Following the growth, $300 \times 300 \mu\text{m}^2$ diode mesas were defined by chlorine-based RIE. Pd/Au (20/200 nm) and Al/Au (20/200 nm) were used as p-type GaN and n-type GaN

contacts **1316** and **1318**, respectively. A schematic cross-section and the $\{10\bar{1}3\}$ plane **1320** of the semipolar LED structure **1300** is shown in FIG. **13**. The electrical and luminescence characteristics of the diode were measured by on-wafer probing of the devices. Relative optical power measurements under direct current (dc) conditions were obtained from the backside emission through the spinel substrate onto a calibrated broad area Si photodiode. Although not presented here, the I-V characteristic and EL spectra as a function of drive current were similar to the blue (~439 nm peak) semipolar LEDs grown on a $\{10\bar{1}1\}$ GaN template on $\{100\}$ spinel. The optical power emission of the LEDs was measured as a function of drive current as shown in FIG. **14**. All measurements were carried out at room temperature.

As shown in FIG. **14**, the output power **1400** increased approximately linearly as the drive current was increased from 10 mA to 90 mA, and then increased sublinearly up to 250 mA. The output power **1400** at 20 mA forward current was 190 μ W, corresponding to an external quantum efficiency (EQE) **1402** of 0.34%. DC power as high as 1.53 mW was measured for a drive current of 250 mA. The EQE **1402** increased as the drive current was increased, attaining a maximum of 0.41% at 50 mA, and then decreased significantly as the forward current was increased beyond 50 mA. This significant decrease in the EQE **1402** with increasing drive current is in contrast to the lack of a decrease in the EQE **1402** with increasing drive current for the blue (~439 nm peak) semipolar LEDs on a $\{10\bar{1}1\}$ GaN template on $\{100\}$ spinel and the green (~525 nm) semipolar LEDs on a $\{10\bar{1}3\}$ GaN template on $\{1\bar{1}00\}$ sapphire. Nevertheless, compared to the other two semipolar LEDs, this semipolar LED demonstrated significantly higher values of peak output power **1400** and peak EQE **1402**, clearly demonstrating the potential for competition with c-plane nitride technology.

The device structures described above constitute the first report of functioning semipolar InGaN-based LEDs. In summary, the present invention demonstrates semipolar LEDs operating in two different spectral ranges, on two different semipolar orientations, and on three different substrates. These include blue (~439 nm peak) semipolar LEDs on a $\{10\bar{1}1\}$ GaN template on $\{100\}$ spinel, green (~525 nm) semipolar LEDs on a $\{10\bar{1}3\}$ GaN template on $\{1\bar{1}00\}$ sapphire, and blue (~440 nm peak) semipolar LEDs on a $\{10\bar{1}3\}$ GaN template on $\{100\}$ spinel. The presentation of these three examples is for illustrative purposes only and should not be interpreted as a limitation on the applicability of the invention to other growth orientations or device structures.

Possible Modifications and Variations

The devices described in the Technical Description comprise light emitting diodes. However, the scope of this invention includes the growth and fabrication of any semipolar (Ga,Al,In,B)N device. Thus, the device structures should not be considered limited to LEDs. Other potential semipolar devices that could be grown and fabricated by the methods of this invention include edge-emitting laser diodes (EELs), vertical cavity surface emitting laser diodes (VCSELs), resonant cavity LEDs (RCLEDs), microcavity LEDs (MCLEDs), high electron mobility transistors (HEMTs), heterojunction bipolar transistors (HBTs), heterojunction field effect transistors (HFETs); and visible, UV, and near-UV photodetectors. These examples and other possibilities still incur all of the benefits of semipolar (Ga,Al,In,B)N devices. This list of possible devices is for illustrative purposes only and should not be construed as a limit on the applications of the invention. Rather, this invention claims any nitride-based device that is grown along semipolar directions or on semipolar planes.

In particular, this invention should offer significant benefits in the design and fabrication of (Ga,Al,In,B)N laser diodes. Such benefits should be especially substantial in long-wavelength laser diodes that have particularly large piezoelectric fields, such as the conceptual device **1500** shown in FIG. **15**. In addition, theoretical calculations indicate that the effective hole masses for compressively strained $\text{In}_x\text{Ga}_{1-x}\text{N}$ quantum wells should decrease monotonically as the crystal angle is increased due to anisotropic strain-induced splitting of the heavy hole and light hole bands [Ref. 9]. Self-consistent calculations of many-body optical gain for compressively strained $\text{In}_x\text{Ga}_{1-x}\text{N}$ quantum wells suggest that the peak gain is most sensitive on effective hole mass and that it increases monotonically with increasing crystal angle [Refs. 17, 18]. Thus, the high carrier densities required to generate optical gain in typical nitride-based laser diodes can be reduced by growing the laser structures on semipolar orientations, especially those with crystal angles closest to $\theta=90^\circ$.

This is reflected in the design of the laser diode **1500** shown in FIG. **15**; of the semipolar orientations that we have demonstrated experimentally, the $\{10\bar{1}1\}$ orientation **1501** has the largest crystal angle ($\theta=62.0^\circ$) and should offer the most substantial improvements in optical gain.

$\{100\}$ Spinel substrate **1502** is used to grow a $\{10\bar{1}1\}$ semipolar GaN template **1504**, and a regrowth of n-GaN layer **1506** is then performed as described above. A n-AlGaIn/GaN Cladding Layer **1508** is then grown, and topped by a n-GaN waveguiding layer **1510**. A MQW active layer **1512** is then grown, with a p-GaN waveguiding layer **1514** grown on the MQW active layer **1512**. Another cladding layer **1516** is then grown, and a p-GaN contact layer is then grown. Ni/Au contact **1520** and Ti/Al/Ni/Au contacts **1522** are then deposited.

The performance of electronic devices should also benefit from this invention. Lower effective hole masses in strained semipolar (Ga,Al,In,B)N layers should result in higher hole mobilities, which should increase the electrical conductivity of semipolar p-type (Ga,Al,In,B)N layers. The higher mobility in strained semipolar p-type (Ga,Al,In,B)N layers should result in improved performance of bipolar electronic devices such as HBTs. The higher p-type conductivity in semipolar nitrides should also result in lower series resistances in p-n junction diodes and LEDs. Furthermore, by altering the crystal growth orientation, the magnitude and direction of the piezoelectric polarization can be tailored to a specific device application. Thus, devices that utilize piezoelectric polarization to generate desirable device characteristics (such as HEMTs) should also benefit from the versatility of this invention.

Variations in semipolar (Ga,Al,In,B)N quantum well and heterostructure design are possible without departing from the scope of the present invention. Moreover, the specific thickness and composition of the layers, in addition to the number of quantum wells grown, are variables inherent to particular device designs and may be used in alternative embodiments of the present invention. For instance, the devices in the preferred embodiment of the invention utilize InGaIn-based quantum wells for light emission in the blue and green regions of the spectrum. However, the scope of the invention also includes devices with AlGaIn-, AlInN-, and AlInGaIn-based quantum wells, which could be designed for light emission in other regions of the spectrum. Furthermore, potential devices such as semipolar HEMTs, HBTs, and HFETs may not even include quantum wells in their respective device structures.

Variations in MOCVD growth conditions such as growth temperature, growth pressure, V/III ratio, precursor flows, and source materials are also possible without departing from

the scope of the present invention. Control of interface quality is an important aspect of the process and is directly related to the flow switching capabilities of particular reactor designs. Continued optimization of the growth conditions should result in more accurate compositional and thickness control of the semipolar thin films and heterostructures described above.

Additional impurities or dopants can also be incorporated into the semipolar nitride films, heterostructures, or devices described in this invention. For example, Fe, Mg, and Si are frequently added to various layers in nitride heterostructures to alter the conduction properties of those and adjacent layers. The use of such dopants and others not listed here are within the scope of the invention.

The preferred embodiment involves first growing a semipolar template by HVPE and then growing semipolar (Ga,Al,In,B)N thin films and heterostructures by MOCVD. However, different growth methods and sequences could be used in alternative embodiments of the present invention. Other potential growth methods include HVPE, MOCVD, MBE, LPE, CBE, PECVD, sublimation, and sputtering. The flow chart in FIG. 4 provides a generalized embodiment that shows how a number of different growth methods and sequences could be used for the practice of this invention.

The scope of this invention covers more than just the four semipolar GaN template orientations cited in the preferred embodiment. This idea is pertinent to all (Ga,Al,In,B)N compositions on all semipolar orientations. For instance, it is feasible to grow {10-11} AlN, InN, AlGaIn, InGaIn, AlInN, or AlGaInN on a miscut (100) spinel substrate. Likewise, it is also feasible to grow {2021} templates if the proper substrate is found. These examples and other possibilities still incur all of the benefits of planar semipolar films.

This invention also covers the selection of particular crystal terminations and polarities. The use of curly brackets, { }, throughout this document denotes a family of symmetry-equivalent planes. Thus, the {10 $\bar{1}$ 2} family includes the (10 $\bar{1}$ 2), ($\bar{1}$ 012), (1 $\bar{1}$ 02), ($\bar{1}$ 102), (01 $\bar{1}$ 2), and (0 $\bar{1}$ 12) planes. All of these planes will be terminated by group III atoms, meaning that the crystal's c-axis points away from the substrate. This family of planes also includes the corresponding nitrogen terminated planes of the same indices. In other words, the {10 $\bar{1}$ 2} family also includes the (10 $\bar{1}$ 2), ($\bar{1}$ 012), (1 $\bar{1}$ 02), ($\bar{1}$ 102), (01 $\bar{1}$ 2), and (0 $\bar{1}$ 12), planes. For each of these growth orientations, the crystal's c-axis will point towards the substrate. All planes within a single crystallographic family are equivalent for the purposes of this invention, though the choice of polarity can affect the behavior of the lateral growth process. In some applications it would be desirable to grow on nitrogen terminated semipolar planes, while in other cases growth on group-III terminated planes would be preferred. The termination of the semipolar plane is largely driven by substrate selection and pretreatment. Both terminations are acceptable for the practice of this invention.

Moreover, substrates other than sapphire and spinel could be used for semipolar template growth. The scope of this invention includes the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices on all possible crystallographic orientations of all possible substrates. These substrates include, but are not limited to, silicon carbide, gallium nitride, silicon, zinc oxide, boron nitride, lithium aluminate, lithium niobate, germanium, aluminum nitride, lithium gallate, partially substituted spinels, and quaternary tetragonal oxides sharing the γ -LiAlO₂ structure.

Furthermore, variations in semipolar (Ga,Al,In,B)N nucleation (or buffer) layers and nucleation layer growth methods are acceptable for the practice of this invention. The growth

temperature, growth pressure, orientation, and composition of the nucleation layers need not match the growth temperature, growth pressure, orientation, and composition of the subsequent semipolar thin films and heterostructures. The scope of this invention includes the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices on all possible substrates using all possible nucleation layers and nucleation layer growth methods.

The semipolar (Ga,Al,In,B)N devices described above were grown on planar semipolar GaN templates. However, the scope of this invention also covers semipolar (Ga,Al,In,B)N devices grown on semipolar epitaxial laterally overgrown (ELO) templates. The ELO technique is a method of reducing the density of threading dislocations (TD) in subsequent epitaxial layers. Reducing the TD density leads to improvements in device performance. For LEDs, these improvements include increased internal quantum efficiencies and decreased reverse-bias leakage currents. For laser diodes, these improvements include increased output powers, increased internal quantum efficiencies, longer device lifetimes, and reduced threshold current densities [Ref. 28]. These advantages will be pertinent to all semipolar planar thin films, heterostructures, and devices grown on semipolar ELO templates.

The preferred embodiment and the alternative embodiments presented above have discussed semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices grown on a foreign substrate. Ideally, though, the substrate would be a free-standing semipolar nitride wafer having a composition lattice matched to the structure to be grown. Free-standing semipolar nitride wafers may be created by removing a foreign substrate from a thick semipolar nitride layer, by sawing a bulk nitride ingot or boule into individual semipolar nitride wafers, or by any other possible crystal growth or wafer manufacturing technique. The scope of this invention includes the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices on all possible free-standing semipolar nitride wafers created by all possible crystal growth methods and wafer manufacturing techniques.

The foregoing description of one or more embodiments of the invention has been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form disclosed. Many modifications and variations are possible in light of the above teaching. It is intended that the scope of the invention be limited not by this detailed description, but rather by the claims appended hereto.

ADVANTAGES AND IMPROVEMENTS

The existing practice is to grow (Ga,Al,In,B)N thin films and heterostructures along the polar [0001] c-direction. The resulting polarization-induced electric fields and inherently large effective hole masses are detrimental to the performance of state-of-the-art nitride optoelectronic devices. The advantage of the present invention is that the growth of (Ga,Al,In,B)N thin films and heterostructures along a semipolar direction could significantly improve device performance by reducing polarization effects and effective hole masses. Prior to this invention, no means existed to grow large area semipolar nitride thin films, heterostructures, or devices.

As an illustration of the potential improvements over existing practice, the device performance of our green (~525 nm peak) semipolar LED grown on a {10-13} GaN template on {1-100} sapphire presented above is compared with the device performance of a typical commercial green spectral range (~525 nm peak) InGaIn LED grown on a c-plane GaN

template. The data presented below were collected from a standard commercial device encapsulated in a hemispherical epoxy dome. The total area of the active region was $300 \times 300 \mu\text{m}^2$, which was the same as the area of the active region of our green semipolar LEDs.

The electrical and luminescence characteristics of the commercial LED were measured by biasing the packaged device. The I-V characteristic of the LED is shown in FIG. 16. Relative optical power measurements under direct current (dc) conditions were obtained from the top of the hemispherical epoxy dome onto a calibrated broad area Si photodiode. The EL spectra and the optical power emission of the LED were also measured as a function of drive current. This data is shown in FIGS. 17 and 19, respectively. All measurements were carried out at room temperature.

As shown in FIG. 16, the I-V characteristic 1600 of the commercial LED exhibited a turn-on voltage of 3.5 V with a series resistance of 28.9Ω . These values are larger than the values of 3.1 V and 14.3Ω for the forward voltage and series resistance, respectively, of our green semipolar LED. The difference in the turn-on voltages of the two LEDs can most likely be attributed to a decrease in the polarization-induced electric fields in the semipolar LED compared to the commercial LED. A decrease in the built-in electric fields should allow current flow in a semipolar diode for smaller separations of the n- and p-type quasi-Fermi levels, resulting in a lower turn-on voltage.

As shown in FIG. 17, the EL spectra 1700 of the commercial LED were also measured at drive currents ranging from 20 to 100 mA. The shift in peak EL as function of drive current is compared for the green commercial LED and our green semipolar LED. As shown in FIG. 18, the commercial device wavelength graph 1800 shifted from 523 nm at 20 mA to 511 nm at 100 mA, spanning a total of 12 nm over 80 mA. Compared to the commercial device, the green semipolar LED wavelength graph 1802 shifted from 528 nm at 20 mA to 522 nm at 250 mA, spanning a total of 6 nm over 230 mA. The decrease in the blue-shift of the emission peak with increasing drive current for the semipolar LED can be attributed to a decrease in the polarization-induced electric fields in the active region of the semipolar LED compared to the commercial LED.

Relative optical output power and external quantum efficiency were also measured for the commercial LED as a function of the dc drive current. The optical power measurements were obtained from the top of the hemispherical epoxy dome onto a calibrated broad area Si photodiode. Such power measurements were intended to provide a measure of the relative output power as function of the drive current, not a measure of the total output power emitted from the commercial LED. As depicted in FIG. 19, the output power 1900 increased sublinearly as the drive current was increased from 10 mA to 130 mA, showing an anomalous jump at 90 mA probably due to heating effects. At 110 mA, the output power saturated, dropping in magnitude at higher current levels until the device died at 140 mA due to heating effects.

Unlike the semipolar LED, the EQE 1902 for the commercial LED peaked at a very low drive current of 10 mA and then diminished significantly at higher drive currents. As shown in FIG. 19, the EQE 1902 of the commercial LED decreased by 65.7% between 10 mA and 130 mA. Comparatively, as shown in FIG. 12, the EQE of the semipolar LED peaked at a relatively high drive current of 120 mA, and then decreased by only about 8% as the drive current was increased beyond 120 mA. The absence of a significant decrease in the EQE with increasing drive currents for our semipolar LEDs is in contrast to the commonly observed phenomenon of a significant

decrease in the EQE of commercial c-plane LEDs working at this wavelength range and similar drive current range. The mechanism behind such a considerable difference in the EQE-I characteristics of our semipolar LEDs and commercial LEDs is unknown at present, although it can be speculated that it may be related to the reduction in the polarization-induced electric fields of semipolar LEDs compared to commercial c-plane LEDs.

Finally, commercial c-plane nitride LEDs do not exhibit any degree of polarization anisotropy in their electroluminescence. Non-polar m-plane nitride LEDs, on the other hand, have demonstrated strong polarization anisotropy along the [0001] axis [Ref. 15]. This polarization can be attributed to anisotropic strain-induced splitting of the heavy hole and light hole bands in compressively strained m-plane $\text{In}_x\text{Ga}_{1-x}\text{N}$ quantum wells. Likewise, for general crystal growth orientations, anisotropic strain-induced splitting of the heavy hole and light hole bands should lead to significant disparities in the x'-polarized and y'-polarized optical matrix elements [Ref. 9]. Thus, the optical emission of semipolar nitride optoelectronic devices should also show significant polarization anisotropy.

The above discussion involves a comparison of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices with commercially available c-plane (Ga,Al,In,B)N thin films, heterostructures, and devices. An analogous comparison can also be made with nonpolar (Ga,Al,In,B)N thin films, heterostructures, and devices. Like semipolar thin films and heterostructures, nonpolar thin films and heterostructures can be used to improve device performance by decreasing polarization effects and effective hole masses. However, high quality nonpolar templates, thin films, and heterostructures are quite difficult to grow, so nonpolar devices are not currently in production. One advantage of semipolar thin films and heterostructures over nonpolar thin films and heterostructures is the ease of crystal growth. The present invention discloses semipolar thin films and heterostructures that have a larger parameter space in which they will grow than nonpolar thin films and heterostructures. For instance, nonpolar thin films and heterostructures will not grow at atmospheric pressure, while semipolar thin films and heterostructures have been experimentally demonstrated to grow from 62.5 Torr to 760 Torr, with potentially an even wider range than that. Thus, unlike nonpolar thin films and heterostructures, semipolar (Ga,Al,In,B)N thin films and heterostructures have shown relatively little correlation between growth pressure and crystal quality.

Another advantage of semipolar planes over non-polar planes is improvement in indium incorporation efficiency. Low indium incorporation efficiency in non-polar a-plane $\text{In}_x\text{Ga}_{1-x}\text{N}$ thin films was a serious issue for the growth of optoelectronic devices on a-plane GaN templates [Ref. 12]. As discussed above, our data suggests that the indium incorporation efficiency in semipolar $\text{In}_x\text{Ga}_{1-x}\text{N}$ thin films is comparable to the indium incorporation efficiency in c-plane $\text{In}_x\text{Ga}_{1-x}\text{N}$ thin films. This high indium incorporation efficiency should help extend the emission range for semipolar $\text{In}_x\text{Ga}_{1-x}\text{N}$ LEDs to longer wavelengths, as already demonstrated by our green (~ 525 nm) LEDs grown on a {10-13} GaN template on {1-100} sapphire.

Nishizuka et al.'s recent disclosure of their {11-22} InGaN quantum wells grown on the sidewalls of patterned c-plane oriented stripes [Ref. 16] provides the closest comparison to our present work. However, this method of producing semipolar thin films and heterostructures is drastically different than that of the current disclosure; it is an artifact of epitaxial lateral overgrowth (ELO). The semipolar facet is not parallel

to the substrate surface and the available surface area is too small to be processed into a semipolar device.

The advantage of the present invention is that it involves the growth and fabrication of semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices on appropriate substrates or templates in which a large area of the semipolar film is parallel to the substrate surface. In contrast to the micrometer-scale inclined-facet growth previously demonstrated for semipolar nitrides, this method should enable large-scale fabrication of semipolar (Ga,Al,In,B)N devices by standard lithographic methods.

The new feature of this invention is the establishment that planar semipolar (Ga,Al,In,B)N thin films, heterostructures, and devices can be grown and fabricated. This has been experimentally confirmed by the authors for (Ga,Al,In,B)N devices grown on three distinct semipolar orientations. The previously discussed advantages will be pertinent to all planar semipolar nitride thin films, heterostructures, and devices.

Process Chart

FIG. 20 illustrates a process chart in accordance with the present invention.

Box 2000 illustrates selecting a semipolar growth orientation.

Box 2002 illustrates selecting a substrate compatible with growth of the selected semipolar growth orientation.

Box 2004 illustrates growing a planar semipolar (Ga,Al,In,B)N template layer on a surface of the substrate.

Box 2006 illustrates growing the semipolar (Ga,Al,In,B)N film on the semipolar (Ga,Al,In,B)N template layer.

CONCLUSION

This concludes the description of the preferred embodiment of the present invention. The foregoing description of one or more embodiments of the invention has been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form disclosed. Many modifications and variations are possible in light of the above teaching, without fundamentally deviating from the essence of the present invention. It is intended that the scope of the invention be limited not by this detailed description, but rather by the claims appended hereto.

What is claimed is:

1. A method for growth and fabrication of semipolar (Ga,Al,In,B)N film, comprising:
 - (a) selecting a semipolar growth orientation;
 - (b) selecting a gallium nitride (GaN) substrate compatible with growth of the selected semipolar growth orientation; and

19

(c) growing one or more planar semipolar (Ga,Al,In,B)N layers on a planar semipolar surface of the GaN substrate by metalorganic chemical vapor deposition (MOCVD), wherein the planar semipolar surface of the GaN substrate has the selected semipolar growth orientation, and an area and quality of the planar semipolar (Ga,Al,In,B)N layers parallel to the surface of the GaN substrate are sufficient to fabricate a semipolar (Ga,Al,In,B)N device.

2. The method of claim 1, wherein the GaN substrate comprises a semipolar gallium nitride wafer.

3. The method of claim 1, wherein the planar semipolar surface of the GaN substrate is grown on a foreign material.

4. The method of claim 1, wherein the planar semipolar (Ga,Al,In,B)N layers form a heterostructure.

5. The method of claim 1, further comprising processing the planar semipolar (Ga,Al,In,B)N film layers into a device.

6. A device fabricated using the method of claim 1.

7. The method of claim 1, wherein the area is at least $300\ \mu\text{m}\times 300\ \mu\text{m}$.

8. The method of claim 1, wherein the area and the quality of the planar semipolar (Ga,Al,In,B)N layers parallel to the surface of the GaN substrate are sufficient to fabricate the semipolar (Ga,Al,In,B)N device using lithographic methods.

9. The method of claim 1, wherein the planar semipolar (Ga,Al,In,B)N layers emit light with a reduced blue-shift in an emission peak with increasing drive current, as compared to a blue shift in c-plane layers operating in a similar wavelength range and similar drive current range.

10. The method of claim 1, wherein the planar semipolar (Ga,Al,In,B)N layers emit light with a reduced decrease in the external quantum efficiency (EQE) with increasing drive current, as compared to a decrease in an EQE in c-plane layers operating in a similar wavelength range and similar drive current range.

11. The method of claim 1, further comprising selecting the semipolar growth orientation from a plurality of available semipolar orientations having a planar surface.

12. A semipolar (Ga,Al,In,B)N film, comprising:

(a) a semipolar growth orientation;

(b) a gallium nitride (GaN) substrate compatible with growth of the selected semipolar growth orientation; and

(c) one or more planar semipolar (Ga,Al,In,B)N layers on a planar semipolar surface of the GaN substrate, wherein the planar semipolar surface of the GaN substrate has the selected semipolar growth orientation, and an area and

20

quality of the planar semipolar (Ga,Al,In,B)N layers parallel to the surface of the GaN substrate are sufficient to fabricate a semipolar (Ga,Al,In,B)N device.

13. The film of claim 12, wherein the GaN substrate comprises a semipolar nitride wafer.

14. The film of claim 12, wherein the planar semipolar surface of the GaN substrate is grown on a foreign material.

15. The film of claim 12, wherein the planar semipolar (Ga,Al,In,B)N layers form a heterostructure.

16. The film of claim 12, further comprising processing the planar semipolar (Ga,Al,In,B)N layers into a device.

17. The film of claim 12, wherein the area is at least $300\ \mu\text{m}\times 300\ \mu\text{m}$.

18. The film of claim 12, wherein the area and the quality of the planar semipolar (Ga,Al,In,B)N layers parallel to the surface of the GaN substrate is sufficient to fabricate the semipolar (Ga,Al,In,B)N devices by standard lithographic methods.

19. The film of claim 12, wherein the planar semipolar (Ga,Al,In,B)N layers emit light with a reduced blue-shift in an emission peak with increasing drive current, as compared to a blue shift in c-plane layers operating in a similar wavelength range and similar drive current range.

20. The film of claim 12, wherein the planar semipolar (Ga,Al,In,B)N layers emit light with a reduced decrease in the external quantum efficiency (EQE) with increasing drive current, as compared to a decrease in an EQE in c-plane layers operating in a similar wavelength range and similar drive current range.

21. The film of claim 12, wherein the planar semipolar (Ga,Al,In,B)N layers include one or more device layers and the semipolar orientation optimizes the device layers' piezoelectric polarization or effective hole mass, as compared to the device layers' piezoelectric polarization or effective hole mass on a different semipolar orientation.

22. The film of claim 12, wherein the semipolar growth orientation is different from a (10-11) or a (10-10) orientation.

23. The film of claim 12, wherein the planar semipolar (Ga,Al,In,B)N layers include one or more device layers and the semipolar orientation is such that at least one of the device layers emits blue light with an external quantum efficiency of at least 0.34% and an output power of at least 190 microwatts, or emits green light with an external quantum efficiency of at least 0.04% and an output power of at least 20 microwatts.
